

# ECE/CS 559 - Fall 2017 - Final Exam.

Full Name:

ID Number:

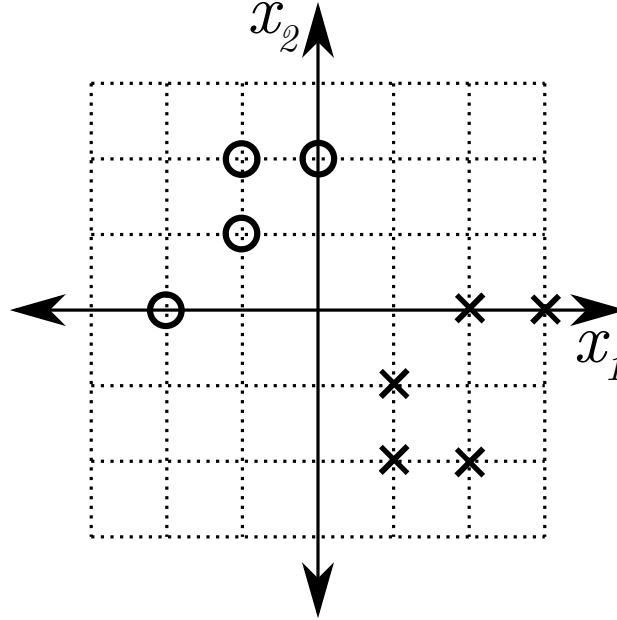

- **Q0 (5 pts):** Attach the e-mail/webpage confirming that you completed the instructor/TA evaluations.
- **Q1 (31 pts):** Consider the Hopfield network below. The activation function is  $\phi(x) = 1$  if  $x \geq 0$ , and  $\phi(x) = -1$  if  $x < 0$ . Recall that the energy function given neuron states  $\mathbf{x}$ , neuron weight matrix  $\mathbf{W}$ , and neuron biases  $\mathbf{b}$  is given by  $E(\mathbf{x}) = -\mathbf{x}^T \mathbf{W} \mathbf{x} - 2\mathbf{b}^T \mathbf{x}$ .

- (a) **(9 pts):** Draw the state transition diagram together with state energy levels for the asynchronous update rule. Indicate the steady state(s) of the network.
- (b) **(7 pts):** Does the network always converge to a steady state under the asynchronous update rule? Justify your answer.
- (c) **(15 pts):** Repeat (a) and (b) for the synchronous update rule.

- **Q2 (30 pts):** This problem will be on SVMs. **Note that neither of the two parts (a) and (b) of this question require solving complex optimization problems.**

- (a) **(15 pts):** Consider the figure below. Each small dotted square is  $1 \times 1$ . Members of  $C^+$  are represented by crosses while members of  $C^-$  are represented by hollow disks. According to this description, we thus have  $C^+ = \{[\frac{2}{0}], [\frac{3}{0}], [\frac{1}{-1}], [\frac{1}{-2}], [\frac{2}{-2}]\}$ , and  $C^- = \{[\frac{-2}{0}], [\frac{-1}{1}], [\frac{-1}{2}], [\frac{0}{2}]\}$ .

Design a **linear SVM** that separates the classes  $C^+$  and  $C^-$ .

Recall that the result of the SVM will be a discriminant function  $g(\mathbf{x}) = g([\frac{x_1}{x_2}])$ . As done in class and the homework problem, your discriminant function should be normalized such that

$$\min_{\mathbf{x} \in C^+} g(\mathbf{x}) = 1 \text{ and } \max_{\mathbf{x} \in C^-} g(\mathbf{x}) = -1.$$

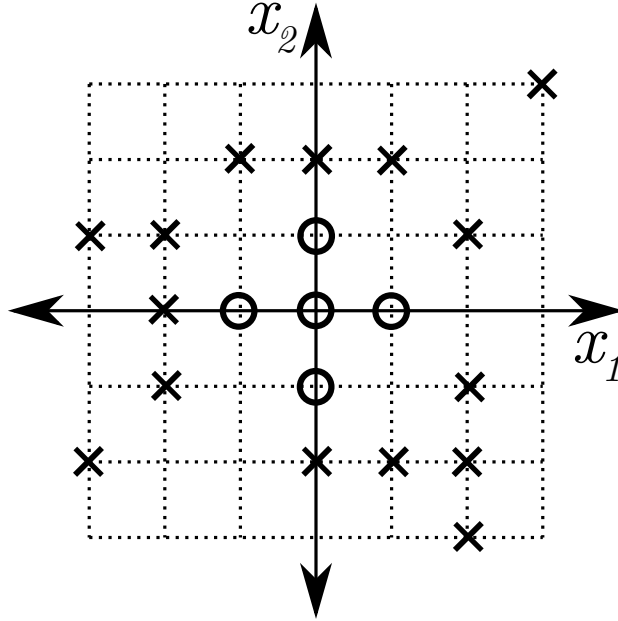

In your solution, you should clearly indicate

- The steps and justifications of your solution to the corresponding SVM design problem.
- The resulting discriminant function  $g(\mathbf{x})$ .
- A sketch of the sets

$$\mathcal{H} = \{\mathbf{x} : g(\mathbf{x}) = 0\}, \mathcal{H}^+ = \{\mathbf{x} : g(\mathbf{x}) = 1\}, \text{ and } \mathcal{H}^- = \{\mathbf{x} : g(\mathbf{x}) = -1\}.$$

- (b) **(15 pts):** Repeat (a) for classes  $C^+$  and  $C^-$  illustrated in the figure below. This time, instead of a linear SVM, you have to design a **non-linear SVM** by picking an appropriate feature mapping/kernel. **Your feature mapping  $\phi(\mathbf{x})$  should depend only on the Euclidean norm  $\|\mathbf{x}\| = \sqrt{x_1^2 + x_2^2}$  of  $\mathbf{x}$ .** For example,  $\phi(\mathbf{x}) = \begin{bmatrix} \|\mathbf{x}\|+1 \\ \|\mathbf{x}\|^2 \end{bmatrix}$  would be a valid feature mapping for this question.

- **Q3 (34 pts):** Let  $\mathbf{x}_1 = \begin{bmatrix} 1 & 1 \end{bmatrix}$ ,  $\mathbf{x}_2 = \begin{bmatrix} 2 & 1 \end{bmatrix}$ ,  $\mathbf{x}_3 = \begin{bmatrix} -1 & -1 \end{bmatrix}$ . We wish to design a one-dimensional SOM with 2 neurons. Let  $\mathbf{w}_{1,0} = \begin{bmatrix} -1 & 0 \end{bmatrix}$  and  $\mathbf{w}_{2,0} = \begin{bmatrix} 0 & 1 \end{bmatrix}$  be the initial weights of the first neuron and the second neuron, respectively.

We recall the standard online learning phase. The patterns are shown sequentially as

$$\mathbf{x}_1, \mathbf{x}_2, \mathbf{x}_3, \mathbf{x}_1, \mathbf{x}_2, \mathbf{x}_3, \dots$$

resulting in the sequence of weights

$$\mathbf{w}_{1,0} = \begin{bmatrix} -1 & 0 \end{bmatrix}, \mathbf{w}_{1,1}, \mathbf{w}_{1,2}, \mathbf{w}_{1,3}, \mathbf{w}_{1,4}, \mathbf{w}_{1,5}, \dots$$

for the first neuron, and the sequence of weights

$$\mathbf{w}_{2,0} = \begin{bmatrix} 0 & 1 \end{bmatrix}, \mathbf{w}_{2,1}, \mathbf{w}_{2,2}, \mathbf{w}_{2,3}, \mathbf{w}_{2,4}, \mathbf{w}_{2,5}, \dots$$

for the second neuron. Thus, for  $n \in \{1, 2, \dots\}$ , the vectors  $\mathbf{w}_{1,n}$  and  $\mathbf{w}_{2,n}$  denote the updated weights after  $n$  patterns are shown to the network. For notational convenience, we let  $\mathbf{x}_n$  denote the  $n$ th pattern shown to the network. For example,  $\mathbf{x}_n = \mathbf{x}_3$  whenever  $n$  is a multiple of 3.

When the  $n$ th pattern  $\mathbf{x}_n$  is shown, we define the winning neuron

$$i_n = \arg \min_{i \in \{1, 2\}} \|\mathbf{x}_n - \mathbf{w}_{i,n-1}\|, \quad n \in \{1, 2, \dots\}$$

as the neuron whose weight vector is closest to  $\mathbf{x}_n$  in terms of the Euclidean distance.

- (a) **(9 pts):** When  $\mathbf{x}_n$  is shown, suppose that we update the winning neuron as

$$\mathbf{w}_{i_n,n} = \mathbf{w}_{i_n,n-1} + \frac{1}{2}(\mathbf{x}_n - \mathbf{w}_{i_n,n-1}),$$

while keeping the loser neuron weights the same (i.e.  $\mathbf{w}_{i,n} = \mathbf{w}_{i,n-1}$  if  $i \neq i_n$ ). Find the weights of both neurons after one epoch of training.

- (b) **(8 pts):** Do the limits  $\lim_{n \rightarrow \infty} \mathbf{w}_{1,n}$  and  $\lim_{n \rightarrow \infty} \mathbf{w}_{2,n}$  exist? In other words, do the weight vectors converge? Justify your answer.

- (c) **(9 pts):** For any real number  $x$ , let  $\lfloor x \rfloor$  denote the largest integer that is less than or equal to  $x$ . For example,  $\lfloor 2.1 \rfloor = 2$ ,  $\lfloor 3 \rfloor = 3$ ,  $\lfloor -1.1 \rfloor = -2$ ,  $\lfloor -5 \rfloor = -5$ . For a vector  $\mathbf{x} = \begin{bmatrix} x_1 & x_2 \end{bmatrix}$ , we let  $\lfloor \mathbf{x} \rfloor = \begin{bmatrix} \lfloor x_1 \rfloor & \lfloor x_2 \rfloor \end{bmatrix}$ .

Now suppose that, when  $\mathbf{x}_n$  is shown, we update the winning neuron as

$$\mathbf{w}_{i_n,n} = \lfloor \mathbf{w}_{i_n,n-1} + \frac{1}{2}(\mathbf{x}_n - \mathbf{w}_{i_n,n-1}) \rfloor,$$

while keeping the loser neuron weights the same (i.e.  $\mathbf{w}_{i,n} = \mathbf{w}_{i,n-1}$  if  $i \neq i_n$ ). Find the weights of both neurons after one epoch of training.

- (d) **(8 pts):** Repeat (b) for the setup in (c).

I will use a slightly different notation.

- (a) Let  $\mathbf{w}_1 = [-1 \ 0]$  and  $\mathbf{w}_2 = [0 \ 1]$ . Show  $\mathbf{x}_1 = [1 \ 1]$  to the network. We have  $\|\mathbf{w}_1 - \mathbf{x}_1\| = \sqrt{5}$  and  $\|\mathbf{w}_2 - \mathbf{x}_1\| = 1$ . So, the second neuron wins, and its weights are updated as  $\mathbf{w}_2 \leftarrow \mathbf{w}_2 + \frac{1}{2}(\mathbf{x}_1 - \mathbf{w}_2) = \frac{1}{2}(\mathbf{x}_1 + \mathbf{w}_2) = [0.5 \ 1]$ . The weight  $\mathbf{w}_1$  remains the same.

Now, show  $\mathbf{x}_2 = [2 \ 1]$  to the network. We have  $\|\mathbf{w}_1 - \mathbf{x}_2\| = \sqrt{10}$  and  $\|\mathbf{w}_2 - \mathbf{x}_2\| = \sqrt{(2 - 0.5)^2 + (1 - 1)^2} = 1.5$  (note that we are using the updated weights). So, again, the second neuron wins, and its weights are updated as  $\mathbf{w}_2 \leftarrow \frac{1}{2}(\mathbf{x}_2 + \mathbf{w}_2) = \frac{1}{2}([2 \ 1] + [0.5 \ 1]) = [1.25 \ 1]$ .

Show  $\mathbf{x}_3 = [-1 \ -1]$  to the network. We have  $\|\mathbf{w}_1 - \mathbf{x}_3\| = 1$  and  $\|\mathbf{w}_2 - \mathbf{x}_3\| = \sqrt{(1.25 + 1)^2 + (1 + 1)^2} > 1$ . So, the first neuron wins, and its weights are updated as  $\mathbf{w}_1 \leftarrow \frac{1}{2}(\mathbf{x}_3 + \mathbf{w}_1) = [-1 \ -0.5]$ .

Hence, after one epoch of training, the updated weights are  $\mathbf{w}_{1,3} = [-1 \ -0.5]$  and  $\mathbf{w}_{2,3} = [1.25 \ 1]$ .

- (b) First observe that in all later epochs, the second neuron will be the winner for patterns  $\mathbf{x}_1$  and  $\mathbf{x}_2$ , and the first neuron will be the winner for pattern  $\mathbf{x}_3$ . It then easily follows that  $\lim_{n \rightarrow \infty} \mathbf{w}_{1,n} = \mathbf{x}_3$ . Consider now the weights of the second neuron. The  $y$ -component will always remain equal to 1. The  $x$ -component at the end of the first epoch was equal to 1.25. At the second epoch, when  $\mathbf{x}_1$  is shown, the  $x$ -component will be updated to  $\frac{1+1.25}{2} = 1.125$ . Then, when  $\mathbf{x}_2$  is shown, the  $x$ -component will be updated to  $\frac{2+1.125}{2}$ . This defines the sequence  $1.25, 1.125, 1.5625, \dots$  where we sequentially apply the functions  $x \mapsto \frac{1+x}{2}$  and  $x \mapsto \frac{2+x}{2}$  to the initial value 1.25. It is not difficult to show that the sequence converges to the “oscillatory limit”  $\frac{5}{3}, \frac{4}{3}, \frac{5}{3}, \frac{4}{3}, \dots$ . Hence,  $\lim_{n \rightarrow \infty} \mathbf{w}_{2,n}$  does not exist. Instead,  $\mathbf{w}_{2,n}$  oscillates between the points  $[\frac{4}{3} \ 1]$  and  $[\frac{5}{3} \ 1]$ .

- (c) Let  $\mathbf{w}_1 = [-1 \ 0]$  and  $\mathbf{w}_2 = [0 \ 1]$ . Show  $\mathbf{x}_1 = [1 \ 1]$  to the network. We have  $\|\mathbf{w}_1 - \mathbf{x}_1\| = \sqrt{5}$  and  $\|\mathbf{w}_2 - \mathbf{x}_1\| = 1$ . So, the second neuron wins, and its weights are updated as  $\mathbf{w}_2 \leftarrow \lfloor \mathbf{w}_2 + \frac{1}{2}(\mathbf{x}_1 - \mathbf{w}_2) \rfloor = [0 \ 1]$ . The weight  $\mathbf{w}_1$  remains the same.

Now, show  $\mathbf{x}_2 = [2 \ 1]$  to the network. We have  $\|\mathbf{w}_1 - \mathbf{x}_2\| = \sqrt{10}$  and  $\|\mathbf{w}_2 - \mathbf{x}_2\| = 2$ . The second neuron wins, and its weights are updated as  $\mathbf{w}_2 \leftarrow \lfloor \frac{1}{2}(\mathbf{x}_2 + \mathbf{w}_2) \rfloor = \lfloor [1 \ 1] \rfloor = [1 \ 1]$ .

Show  $\mathbf{x}_3 = [-1 \ -1]$  to the network. We have  $\|\mathbf{w}_1 - \mathbf{x}_3\| = 1$  and  $\|\mathbf{w}_2 - \mathbf{x}_3\| = \sqrt{8}$ . So, the first neuron wins, and its weights are updated as  $\mathbf{w}_1 \leftarrow \lfloor \frac{1}{2}(\mathbf{x}_3 + \mathbf{w}_1) \rfloor = \lfloor [-1 \ -0.5] \rfloor = [-1 \ -1]$ .

Hence, after one epoch of training, the updated weights are  $\mathbf{w}_{1,3} = [-1 \ -1]$  and  $\mathbf{w}_{2,3} = [1 \ 1]$ .

- (d) It is easy to see that there will be no more updates on the weights and we have  $\lim_{n \rightarrow \infty} \mathbf{w}_{1,n} = \mathbf{x}_3$  and  $\lim_{n \rightarrow \infty} \mathbf{w}_{2,n} = \mathbf{x}_1$ .
